Title: Cyberspace or Face-to-Face: The Teachable Moment and Changing Reference Mediums

Authors: Christina M. Desai, Science Reference Librarian, Southern Illinois University Carbondale

Stephanie J. Graves, Humanities Reference Librarian, Southern Illinois University Carbondale

Abstract: This article considers the teaching role of reference librarians by studying the teachable moment in reference transactions, and users’ response to that instruction. An empirical study of instruction was conducted in both virtual and traditional reference milieus, examining three services: IM (Instant Messaging), chat, and face-to-face reference. The authors used the same criteria in separate studies of all three to determine if librarians provided analogous levels of instruction and what factors influenced the likelihood of instruction. Methodology employed transcript analysis, observation, and patron surveys. Findings indicated that patrons wanted instruction in their reference transactions, regardless of medium, and librarians provided it. However, instructional techniques used by librarians in virtual reference differ somewhat from those used at the reference desk. The authors conclude that reference transactions, in any medium, represent the patrons’ point-of-need, thereby presenting the ideal teachable moment.
Cyberspace or Face-to-Face:  
The Teachable Moment and Changing Reference Mediums

The teachable moment, sometimes referred to as the “aha” moment, is defined as the:

**moment of educational opportunity**: a time at which a person, especially a child, is likely to be particularly disposed to learn something or particularly responsive to being taught or made aware of something.¹

Reference queries present prime examples of the teachable moment. They catch researchers at their point of need and provide opportunities for one-on-one personalized instruction and hands-on learning. Reference work in academic libraries has been deeply affected by technology. One of its most noticeable effects has been on librarians’ instructional role. As more patrons access library resources remotely and fewer visit the reference desk, opportunities for face-to-face instruction decrease. As they become more computer-savvy, patrons may feel that the need for instruction also decreases. To what extent are librarians instructing patrons during reference transactions? Is there a difference in the amount and type of instruction offered in virtual reference such as IM (Instant Messaging) or chat? Do librarians at the physical reference desk provide more instruction? Do they provide it more often? Are they taking advantage of those teachable moments?

In today’s ideal reference model, librarians show patrons how to find information rather than simply provide answers. RUSA’s "Guidelines for Behavioral Performance of Reference and Information Service Providers"² emphasizes the importance of instruction in all reference environments, including virtual reference. We might assume that it is simpler to provide instruction face-to-face and therefore more common at the physical reference desk, but is this true? The authors examined this question as it relates to IM/chat reference in two previous studies. Chat was defined as commercial software developed for libraries, and IM as free or home-grown messaging software without co-browse capability. The current study builds on the previous two studies by comparing instruction via IM and chat to instruction at the traditional reference desk, using the same criteria.

The purpose of Study 1, conducted in 2005, gauged the amount of instruction being offered through IM reference.³ Using transcript analysis and a user survey, the authors determined how often librarians provided instruction and under what conditions they were most likely to provide it. They also inquired into patrons’ desire for and willingness to receive instruction and their perception of actual learning. The authors also developed a classification of teaching techniques employed by librarians and measured their frequency.

The following summer the home-grown software for the service was replaced with commercial chat software with co-browsing capability. To test whether the co-browsing feature made a difference in the amount and type of instruction offered through chat, the authors conducted another study (Study 2), comparing the results from the new software
to the original home-grown product. The same criteria and methodology were used to evaluate the likelihood and frequency of instruction, but this time the effect of co-browsing on instruction and on patrons’ perception of learning also was studied.

The purpose of the present study is twofold. It compares the frequency and types of instruction that occur during reference in two mediums, traditional (in-person) and virtual (IM and chat) reference. Secondly, as with the previous studies, it also gauges whether users want or are willing to accept instruction and whether they feel they learned anything from the reference transaction. The current study of the physical reference desk follows as closely as possible the methodology used in the first two studies of the virtual reference milieu.

Literature Review

Studies assessing information literacy programs and traditional bibliographic instruction (BI) classes abound. However, few studies have actually measured the instructional activity at the reference desk. Jacoby and O’Brien’s study touches on instruction as one aspect of assessing reference service. It surveyed undergraduates and found that nearly 64% “learned about new resources during the reference encounter” and many also acquired strategies for finding information. However, rather than focusing on effective instructional techniques, most of the debate has centered on whether librarians should be teaching at the reference desk at all. Schiller provides one of the early arguments against instruction during reference work, and noteworthy figures such as Bill Katz have also expressed strong opinions on the matter.

Emphasis has shifted in recent years to classroom bibliographic instruction. However, some argue that point-of-need assistance is more effective. In a focus group study at Johns Hopkins, Massey-Burzio found that students were dissatisfied with reference when “Information Desk staff did not go to the computers with them to explain things…” She posited that point-of-need assistance is more successful than classroom instruction. Saunders found that bibliographic instruction may make a more sophisticated, but not necessarily a more self-sufficient searcher. He found that “the number of reference questions will increase by anywhere from two to seven questions for each person receiving bibliographic instruction.” McCutcheon and Lambert echo this connection, calling for more communication between classroom instructional librarians and reference librarians to increase learning opportunities at the reference desk.

The proliferation of technology starting in the 1980s blurred the lines between providing traditional reference and providing technical assistance. Many supposed that information systems would obviate the need for traditional reference altogether. Yet newer interfaces designed for end-users made instruction more crucial than ever because, while reference librarians no longer simply connected users to print sources, neither could they expect patrons to find, navigate, and evaluate electronic systems without help. Hope, Kajiwara, and Liu in a review article assert that the advent of the Internet has expanded, not reduced, the librarian's instructional role. Tyckoson believes that “…the complexity of the modern library requires us to continually re-instruct existing library users. New technologies, new services, and new sources are not self-evident, even to the most experienced users. . . . Instruction is now more important and more central to the role of
the library than it has been at any time in the past, and there is no reason to believe that this need will change in the future.”

In an early study of the impact of technology on instruction, Tenopir found that academic librarians were spending more time, not less, on instruction, particularly one-on-one instruction, because of the new electronic formats. However, though one of Tenopir’s survey respondents concurred, she also felt she should have been spending more time teaching all along. She felt that recommending a particular index was not sufficient because the patron was still often unsuccessful. Tenopir state that: “These librarians feel technology helped get them out of a bad habit of assuming everyone was getting satisfactory results once they had been directed to a resource or taught the rudiments of its use.”

Those were the early days of adjusting to electronic sources. Today online sources have become so ubiquitous that many students have never used a print index. Electronic sources have become much more user friendly. Yet, training and hands-on practice are as important as ever. An Elsevier study of user behavior found that “A higher level of search skills (and greater knowledge of literature) gained through experience and training enabled senior researchers to answer questions and locate key articles in an average of 5-10 minutes instead of the 30-60 required by graduate students.” If graduate students in science and technology disciplines, presumably computer literate and somewhat experienced with research, are performing inefficient and unsuccessful searches, it is likely that undergraduates are even more at a loss. The need for instruction does not seem to diminish with improvements in technology. Yet many students fail to realize they need help learning how to do research. In an article applying competency theory to the reference situation, Gross suggests that the least competent information seekers are also the least likely to recognize their need for guidance and instruction in their information search. It is therefore up to reference librarians to recognize the need for instruction and provide it.

Like studies of instruction at the reference desk, studies of instruction via chat reference are very few. This lack of research is surprising given that RUSA “Guidelines” stress the importance of instruction in all reference situations, regardless of the medium. Several articles on using chat for instruction relate not to chat reference services but to such applications as holding online office hours for distance learners or for supplementing online tutorials. Articles cited in the authors’ previous research by Beck and Turner, Green and Peach, Ellis, Ward, and Woodard remain the primary examples of studies of instructing via reference, either with techniques specific to chat or by applying techniques from the physical reference desk to the virtual desk. A special issue of The Reference Librarian devoted to digital reference makes few mentions of instruction aside from the article on communication strategies. One author even cautions that librarians who are used to providing detailed instruction via email reference will “not have that luxury in chat reference.” Articles reporting on chat reference user satisfaction almost never ask about learning. One exception is an article by Broughton; of the 209 responses, 136 reported instances of learning (such skills as keyword vs. subject searching, search strategy construction, correct citation style, etc.).
Some articles on assessment of chat reference services make passing mention of best practices that relate to learning, such as the article by Ronan, Peakes, and Cornwell in which chat transcript analysis revealed several instances of page pushing without any explanation of how to get to the page. A more recent article by Zhou, Love, Norwood, and Massia measures staff performance against the RUSA “Guidelines” using a strict definition of instruction, they found only about two thirds of their transcripts showed evidence of teaching. These authors looked for instruction only in the transcripts related to research questions (70%), assuming that other question types do not call for instruction. A recent assessment article by Paster, et al. takes a similar approach, using patron surveys to measure learning as one indication of patron satisfaction. Most assessment articles, however, do not mention instruction, including the article by Novotny, which reviews various best practices guidelines by which to assess virtual reference quality.

The present study appears to be the first to compare instructional activity in both physical and virtual reference mediums, using the same criteria. This and the authors’ previous two studies use both transcripts and survey data to determine librarian instructional activity. All three studies also measure patrons’ attitude toward instruction and their perception of learning.

Method

The authors when considering methodology had to decide between an obtrusive or unobtrusive protocol, and make sure that necessary safeguards were in effect. Earlier empirical studies of reference focused on the accuracy of the answers provided. Later studies countered with work on what determines "satisfaction" and "willingness to return." To ensure impartiality, these studies used an unobtrusive method, which involved hiring proxy patrons to ask a set of pre-determined, usually factual questions at various reference desks. The procedure is considered unobtrusive because the librarians are not informed that they are being tested and therefore it is assumed that they do not alter their normal response.

The alternative, obtrusive studies, may suffer from a phenomenon known as the Hawthorne effect. As usually summarized, this is the presumption that behavior of experimental subjects will change if they know they are being observed. The notion is based on industrial experiments conducted in the 1930s by Roethlisberger and Dickson in which production levels increased with changes in experimental conditions, regardless of what the changes were. Later reviews of this research found many overlooked factors at work, such as changes in pay structure, access to production totals, peer pressure, peer support, and increased skill. Finally it was not the case that production increased with every change in conditions. In the many subsequent empirical studies of the Hawthorne effect, only a few could replicate the effect or support its validity. A more important variable may be the subjects’ perception of the purpose of the research and attitude toward that purpose. Thus, while it makes intuitive sense to assume that workers who are watched will put their best foot forward, it has not been conclusively proven that this is the case.
It is a truism of reference practice that patrons’ initial questions seldom express their real information needs, and few questions asked in an academic library are strictly factual.\textsuperscript{35} While in an unobtrusive study, librarians may not alter their behavior, the behavior of proxy patrons remains an issue. Because their information needs are real, actual patrons will elaborate if the librarian probes, and are likely to participate in the information seeking process more actively than proxies. Jensen objects to the unobtrusive proxy method in studies of chat reference both because it is an unfair imposition on the resources of the library and also because it could result in skewed research results, since “The chat discourse of an information professional or trainee presenting a sham query is very likely to differ from that of a genuine questioner.”\textsuperscript{36} To avoid this artificiality, the authors chose obtrusive direct observation of real reference transactions at the physical reference desk. Whitlatch, in a study of reference research methodologies, recommends the obtrusive approach with the caveat that “Safeguarding against observational bias also requires training observers thoroughly and may require using more than one observer.”\textsuperscript{37} She also advises using more than one method for each study “because the strengths of one method often compensate for the weaknesses of another.”\textsuperscript{38} The current study implemented these safeguards by using three trained observers and unobtrusive patron surveys to corroborate results.

The authors’ previous studies of virtual reference could be considered unobtrusive. Certainly, no one was physically present in the virtual librarian’s office during reference transactions. However, transcript analysis was not strictly unobtrusive. Librarians knew that their transcripts were stored and that those transcripts would be used for training and research. Much like the reference desk where other librarians can overhear conversations, online reference librarians are aware that other librarians can view their chat transcripts at any time. Therefore there is little difference in the degree of obtrusiveness between the two virtual studies and the physical reference desk study. In all three studies, Human Subjects compliance required informed consent of the subjects, i.e., the librarians. If the observations did affect behavior, they would likely have affected both mediums equally. It should also be noted that the observers were peers, not in a position of authority over the observed librarians. Observed librarians were told only that this was a study of reference, not that the researchers were looking for instances of instruction. Nor were the observations or patron surveys shared with librarians.

Both librarians and paraprofessionals were observed, since both groups provided a substantial amount of reference. The paraprofessionals were all long-term employees with considerable experience and expertise in providing reference. Many of them readily volunteered to staff the IM service when it began and continue to staff both online and physical reference along with librarians. Names of service providers were not recorded in the data collected. For the sake of simplicity, all staff members will be referred to as librarians unless otherwise noted.

The authors developed an observation matrix of instructional activities based on Studies 1 and 2, and conducted a pilot test for one week. As in the studies of virtual reference, each transaction was evaluated for instructional activity and assigned to one of six categories:

- **C1. Patron asked for and received instruction.**
- **C2. Patron asked for but was not given instruction.**
C3. Patron did not ask for but was given instruction.
C4. Patron did not ask for, and the librarian did not give instruction.
C5. No instruction was possible, given the nature of the question, i.e., library policy questions.
C6. Instruction was not asked for, and not given, but was offered by the librarian.

Category 5 questions were eliminated from analysis since they have no bearing on instruction.

Categories were assigned based on patrons’ initial queries. Questions such as “How do I …,” “Can you help me find…,” and “Can you show me how…” were defined as requests for instruction. Initial queries such as “Where is…” [asking for physical location], “Do you have…,” and statements such as “My article won’t print” were defined as not asking for instruction. Providing instruction was defined as showing the patron how to search by one or more of the following activities: suggesting appropriate resources, terms, limits, etc., leading the patron step-by-step through the research process, providing mini-lessons on the meaning of library jargon or concepts, or modeling the information seeking process by describing the full sequence of steps. In addition, observers collected data on actions analogous to co-browsing in chat, such as turning the screen toward the patron to demonstrate the steps in the search process, pointing to portions of the screen or encouraging the patron to use the mouse or type into the search boxes. After minor modifications based on the pilot test, observations were conducted during the hours when chat reference was also offered. These hours were chosen as the busiest times of the day for both physical and virtual reference.

Observation of the Information Desk and coding were done by the authors and a graduate assistant hired for the purpose. Data collection was to have covered a seven week period, as in the earlier two studies. Observation began as scheduled during spring semester, 2006 during the hours when the chat service was also offered, for a total of 29 hours of observation per week. During this period, the library was undergoing extensive renovation and part of the building was closed. While the noise, physical appearance, and reduced space in the library meant that fewer patrons used the library building, the Information Desk continued to function as usual.

An unforeseen construction problem forced an end to data collection during the sixth week. To ensure the safety of staff and library users, the building was temporarily shut down. Though temporary satellite reference desks were quickly set up in other locations on campus, the study had to be suspended because these desks were staffed for limited hours and mostly by graduate assistants. While it would have been very interesting to observe how well reference and instruction were being offered under these trying conditions, it could not be attempted because the graduate assistants had not been cleared for study by the campus Human Subjects committee. Despite the construction, the amount of data collected during these five weeks far exceeded the amount collected during the seven weeks of the virtual reference studies. Students still use the traditional reference desk far more than any form of virtual reference. Analysis of the high volume of data collected at the traditional desk showed that the instructional patterns were similar from week to week, so we may assume that the missed weeks’ observations would not have significantly affected the results.
As in the studies of IM and chat reference, Information Desk patrons were asked to fill out a survey. The surveys were designed to gauge users’ attitudes toward receiving instruction and their perception of learning from the reference transaction. The surveys were voluntary and anonymous. Patrons could be faculty, staff, students, or community members. In both Study 1 and the current study, the patrons’ surveys and their corresponding reference transactions were matched using the initial query. Knowing what happened during the reference transaction helped explain survey responses. This linking was not possible in Study 2 due to limitations of the chat software. Results from the Information Desk and corresponding patron surveys were compared with results from Study 1 and 2.

**Findings**

**Observation Matrix & Transcript Analysis**

The number of transactions at the physical reference desk far exceeded those in virtual reference. In Study 1, the study of IM service, 169 transcripts were reviewed. In Study 2, the study of chat service with co-browse capability, 136 transcripts were reviewed. Study 3, the study of the Information Desk, recorded the most transactions with a total of 567 observations. Each transaction was coded for one of the six instructional categories. In each case, reference transactions coded as Category 5 (C5) were removed from the total. C5 were those instances where instruction was not possible given the nature of the question or situation. An example would be asking for assistance in clearing a paper jam. Including C5 would have skewed the results since librarians cannot be held responsible for providing instruction in instances where it is not possible or appropriate. Eliminating C5 transcripts reduced the number of transactions in each study as follows:

- **Study 1:** 146 transcripts
- **Study 2:** 118 transcripts
- **Study 3:** 273 observations

The Information Desk had a much greater percentage of C5 occurrences. In Study 1, C5 questions accounted for 12% and in Study 2, 13% of the questions. However, in Study 3, C5 transactions accounted for 52% of all recorded transactions. The current study showed that librarians at the physical Information Desk fielded many more non-instructive questions. This corroborates anecdotal evidence from staff who often complain about spending time fixing printer problems and pointing out the location of the stapler. All subsequent statistics are based on total transactions minus C5.

Chart 1 depicts the percentage of each category in Study 3, the study of the Information Desk.
Of the 273 transactions, 46% were identified as C1 (patron asked for and received instruction). C3 (patron did not ask for but was given instruction) followed with 43%. Combining these two categories reveals that patrons received instruction 89% of the time. C4 accounted for only 6%, and C2 only 5%. As C2 and C4 represented a failure by the librarian to provide instruction, it is reassuring that combined they totaled a small fraction of the reference transactions (11%). There were no instances of C6 (instruction was not asked for, and not given, but was offered by the librarian).

Chart 2 compares Studies 1, 2, and 3 by percentage of each category to gauge differences across the three reference mediums.

**Category 1 (C1): Patron asked for and received instruction.**
These transactions formed the largest group in all three studies, showing that patrons were asking for instruction, regardless of reference medium. Study 2 figures for C1 were
9% higher than in Study 1. C1 transactions in Study 3 were much closer to Study 1’s figures. The discrepancy may be explained by the entry screen for chat reference in Study 2. Transcript analysis revealed many patrons misinterpreted the entry screen in Study 1 and used it as a site search or search engine, often entering a single keyword or phrase rather than a complete sentence or question. A query consisting of a single word could not be interpreted as a request for instruction. In Study 2, patrons had to click on several icons and then fill out a form to enter chat reference. Consequently, patrons seemed to understand that they were asking a question of a librarian and phrased their queries accordingly. Problem statements, such as “My article won’t print,” were not coded as requests for instruction and these occurred more often at the Information Desk. These two factors may account for the lower number of C1 transactions in Studies 1 and 3.

Category 2 (C2): Patron asked for but was not given instruction. Transactions coded as C2 were lowest in Study 1 at 2% and highest, at 5%, in Study 3. While the numbers were remarkably low, this category does represent a failure of the librarian to provide instruction, even when asked to do so by the patron. The higher number of C2 transactions at the reference desk is disturbing. Perhaps the heavy volume of questions at the physical desk reduced the time available for instruction. However, this is supposition only.

Category 3 (C3): Patron did not ask for but was given instruction. The largest discrepancy in any of the categories appeared in Category 3. C3 transactions dropped 10% from Study 1 to Study 2, from 40% to 30%, then rose 13% in Study 3 to a high of 43%. Why the dip in Study 2? As with the discrepancy in Category 1, the authors speculate that the difference was attributable to the more formalized chat entry screen in Study 2. There were no single-word or phrase queries in Study 2. Single word or phrase queries would have been coded as the patron not asking for instruction; these were prevalent in Study 1. The authors also speculate that the rise in Study 3 may have to do with the social nature of the information desk. Patrons would not approach the librarian at the desk with a single word or phrase, as in Study 1. However, they were more apt to approach the librarian with a problem statement, which was coded as the patron not asking for instruction. Common examples were students who approached the Information Desk with the statement, “My account has been disabled.” While these patrons clearly did not ask for instruction, librarians often conducted a detailed instructional session with these patrons to show them how to unlock and manage their network accounts.

Category 4 (C4): Patron did not ask for and the librarian did not give instruction. Category 4 transactions were relatively even in Studies 1 and 2 (12% and 14% respectively). In Study 3, this particular category totaled 6%. This follows logically; since patrons at the Information Desk get instruction more often, this category must be lower.

Category 6 (C6): Instruction was not asked for, and not given, but was offered by the librarian. Category 6 dropped from 3% in Study 1 to 1% in Study 2 and finally to 0% in Study 3. Transcript analysis of Studies 1 and 2 showed that this category was assigned to
transactions in which the online librarians first gave an answer, then offered instruction, but patrons logged off before the librarian could proceed. Similar behavior is unlikely to occur at the physical reference desk, where body language cues would alert librarians to patrons’ openness to instruction and social convention would prevent patrons from walking away without answering.

Did reference medium impact the likelihood of instruction? Combining specific categories helped answer this question. Categories 1 and 3 represented transactions in which patrons received instruction. In Study 1, combining these two categories showed that patrons received instruction 83% of the time. Study 2 had an 82% rate of instruction. Study 3 ranked highest with 89%. While the rate of instruction remained remarkably similar across all three studies, instruction was slightly more likely at the physical information desk.

The results of Studies 1 and 2 showed that patron question format affected the likelihood of instruction. In both studies of virtual reference, patrons who asked for instruction (C1 and C2) received it 95% of the time. In Study 3, patrons who asked for instruction in face-to-face reference received it 94% of the time. These consistent results show that the reference medium, be it virtual or physical, did not have an impact on the likelihood of instruction if the patron requested it.

Conversely, results showed that the reference medium did affect the likelihood of instruction for those patrons who did not ask for instruction, represented by Categories 3, 4, and 6. C3 represented those who received instruction without asking for it. Therefore, dividing C3 by the total for all three categories gives the rate of instruction when not requested. In a comparative analysis of Study 1 and Study 2, the rates were 77% and 68% respectively. The authors hypothesized that the decrease was due to staff discomfort with the commercial chat product introduced shortly before Study 2 began. The same hypothesis may explain the higher rate of instruction for those who did not ask for it (87%) in Study 3. Librarians at the Information Desk have years of experience and are experts at that particular reference medium. They obviously feel comfortable asserting themselves and acting as instructors, even when not directly prompted by the patrons’ queries.

While the analysis above emphasizes the differences between virtual and physical reference mediums, it is worth noting that the percentages remain strikingly similar across all three studies. The authors feel confident that librarians at this library are providing instruction most of the time regardless of medium. If our goal is to provide consistent service, this data shows that librarians are on the right track. The reference medium did not significantly alter librarians’ willingness or ability to provide instruction.

Does the likelihood of instruction differ, however, if the patron is served by a librarian as opposed to a paraprofessional? Librarians and paraprofessionals staff both in-person reference and virtual reference, and any inconsistency in service should be noted. The rate of instruction was determined by totaling Categories 1 and 3 for librarians and for paraprofessionals, and dividing by the total number of transactions for that group. Information from Study 2 showed that paraprofessionals provided instruction 74% of the time while librarians did so 87% of the time. Study 3 mirrors these findings, with
librarians providing instruction 90% and paraprofessionals 81% of the time. The difference is understandable, given that librarians are trained and dedicated to information literacy skills. However small the difference, it indicates that more training is necessary for paraprofessionals if consistency of service is to be maintained.

Face-to-face reference has a component less readily available in virtual reference, the ability to confer with colleagues. Chat products often include the ability to hold private conversations with another librarian while helping a patron. Some chat platforms enable transferring patrons between online librarians. However, both features require that more than one librarian be online simultaneously. Virtual services studied in this research were staffed by only one librarian at a time; therefore, there were no instances of consultation. In contrast, in Study 3, 29 instances of librarians conferring during face-to-face reference were recorded. In addition, in another 33 cases, patrons were referred to another librarian. The ability to confer is clearly a benefit of face-to-face reference.

Much of the literature on virtual reference speaks of the lack of non-verbal cues in the online environment. To see if non-verbal cues were impacting the likelihood of instruction, a section was added to the observation matrix in Study 3. Observers recorded the physical behaviors and facial expressions of the patron. After recording behaviors, the observers answered yes or no to the statement “The patron was interested in learning.” Behaviors indicating interest included: leaning in toward the librarian; watching the computer screen; taking notes; and engaging in active dialogue with the librarian. Behaviors indicating patrons were not interested included: looking away during the reference transaction; talking on a cell phone; talking with other patrons; and crossing their arms. While these non-verbal behaviors were not necessarily steadfast indicators, librarians could make assumptions about a patron’s willingness to accept instruction based on these non-verbal cues.

There were 259 observations in which non-verbal behaviors were recorded. Only 62 (24%) indicated lack of interest. Surprisingly, 5 of these patrons actually phrased their initial query in such a way that it coded as C1 or C2 (patron asked for instruction), but their body language told a different story. The majority of the remaining 76% indicated interest in learning by non-verbal cues; most of them also phrased their query as a request for instruction. Did non-verbal cues affect the likelihood of instruction? If a patron appeared uninterested in learning, did the librarian still practice instruction? Categories 1 and 3 divided by the total represent the rate of instruction. For those who exhibited non-verbal behaviors indicating interest in learning, there was a 94% rate of instruction, as opposed to 73% for those who exhibited lack of interest. Non-verbal clues did seem to have an impact. In summary, it seems that librarians were influenced by their perceptions of patrons’ interest in learning. They are alerted to the teachable moment by both initial query and by body language.

All three studies showed that librarians were providing instruction via the reference transaction. What kinds of instruction were they practicing? Each interaction in all three studies was coded for the following instructional practices:

A Modeling: Librarian finds and gives the needed information, then outlines the steps to locate it but does not make sure the patron is following along.
B. Resource Suggestion: Librarian suggests print or electronic resources such as the library catalog, a database, or URL.
C. Terms Suggestion: Librarian suggests appropriate keywords, subject headings, Boolean operators, or limits.
D. Leading: Librarian leads the patron step-by-step to the needed information.
E. Lessons: Librarian explains library or research terminology such as the peer-review process.

Multiple codes could be assigned for each transaction, because many librarians used multiple instructional techniques in any given transaction. But each code was used only once, despite the number of times it may have occurred during the transaction. Totals for each code were then divided by the total number of transactions, to show which were being used most often. Chart 3 shows the results for Study 3. Percentages do not equal 100% since multiple codes could be used in each transaction.

Librarians practicing face-to-face reference favored Leading as an instructional technique. This technique, walking the patron through a process in small sequential steps, occurred in 63% of the transactions. Resource Suggestion followed with 52%. The third most common instructional practice was Modeling, with a 47% rate. Terms Suggestion ranked fourth at 22%, and Lessons came in last at 17%.

Analysis of instructional techniques also was applied to Studies 1 and 2 to measure the rate of each technique in the different reference mediums. Did librarians practice different instructional techniques in virtual as opposed to face-to-face reference? Results showed that this was indeed true. Chart 4 compares the five instructional techniques across all three studies: IM, chat, and face-to-face reference.
Chart 4: Comparative Analysis of Instructional Methods

Chart 4 shows that Modeling occurred much more often in face-to-face interactions, 47% of the time, as opposed to 23% in both IM and chat. In Resource Suggestion, face-to-face reference ranked lowest at 52%. Librarians in IM were more likely to practice Resource Suggestion at 60%, and chat librarians even more so at 77%. Terms Suggestion remained comparable across all three mediums at 29%, 20%, and 22% respectively. However, Study 3 showed another large difference in Leading at 63%. Only 42% used Leading in Study 1 and even fewer, 25%, in Study 2. The least used instructional practice in all three studies, Lessons, ranked highest in face-to-face reference at 17%. It was almost nominal in Studies 1 and 2 at 5% and 3% respectively.

Clearly, librarians practiced different instructional techniques in different reference mediums. Why? Perhaps some instructional techniques are more suited to in-person reference rather than the online environment. For instance, the explanation for the dramatic increase in Lessons (on library terminology or theories and complex processes) during Study 3 seems clear. Complex ideas can be more easily conveyed in fluid conversation with a patron than in the staccato nature of chat where it is not practical to type long paragraphs. Likewise, the rise in Modeling and Leading can be explained by librarians’ comfort with the reference medium, lack of technical difficulties, and the personal nature of face-to-face reference. However, more study would be needed for a definitive answer.

Questionable reference practices were also recorded in all three studies. Two specific questionable practices were identified, page pushing and citation pushing. Page pushing was defined as directing a patron to a web page without explaining how to get there or how the librarian knew to go there. In the virtual environment, librarians can choose to page push by manipulating the patrons’ web browsers. In face-to-face reference, the librarian can click on or go to websites without showing or explaining the process to the patron. Citation pushing is similar in that librarians give a citation or call number without explaining how they garnered that source. Both are questionable practices because they
Page pushing occurred in 63 instances in Study 1, 0 in Study 2, and 33 in Study 3. In previous analyses, the authors speculated that due to insufficient training, staff may have been unaware of how to push pages in the new chat software used in Study 2. The majority of page pushes in Study 3 were instances in which the librarian went directly to the catalog without explaining what it was or how to gain access to it. For the novice patron, this is an important first step that should not be ignored.

Frequency of citation pushes saw a marked difference in each medium. Study 1 showed 56 counts of citation pushing, Study 2 had only 22, and Study 3 had fewer still at 19. This may be due to the fact that visual demonstration of citation retrieval is not possible in IM reference, whereas it is feasible in chat with co-browse, and easy in face-to-face reference.

**Survey Analysis**

Similar patron surveys were administered in all three studies. The surveys administered in Studies 1 and 2 were web-based; surveys in Study 3 were paper-based. Questions relative to co-browsing capability were added to Survey 2. Likewise, questions relative to the reference desk were added to Survey 3. Response rates were more generous in the online surveys. Survey 1 had 50 respondents, a 30% response rate. Survey 2 had the highest response rate at 62 respondents, or 46%. Survey 3, the paper survey, had 88, for a 16% response rate.

Survey responses are summarized in Chart 5. Morris Messenger refers to the IM and chat services.

Responses from IM and chat users were fairly consistent, but there were notable differences between virtual and physical mediums. First time respondents accounted for over 70% of online reference patrons. Survey results showed the opposite was true of physical reference, with 86% having used the Information Desk before. Patrons in all three studies indicated willingness to return, an indicator of patron satisfaction. Face-to-face reference received the highest proportion with 99% willing to use the service again. IM followed with 98%, and chat with 93% willingness to return.

Reference librarians may believe in the teachable moment, but do patrons actually want instruction? All three surveys indicated that they do. While all the survey results were similar, more survey respondents at the physical reference desk indicated a desire to learn. Of these, 57% “Definitely” wanted the librarian to teach them how to find information for themselves. This compared to 55% in chat and only 46% in IM reference. Respondents who indicated instruction “Would be nice” made up an additional 27% in both physical and chat reference and 16% in IM reference. Apathetic responses (“Didn’t care”) differed with 30% in Survey 1, 15% in Survey 2, and only 10% in Survey 3. Finally, respondents could answer that they were not interested in instruction and they wished the librarian would “Just find it for me.” A small minority preferred this, with 8% in IM, 3% in chat, and 6% at the Information Desk. Adding “Definitely,” “Would be nice,” and “Didn’t care” responses gave the total number of patrons open to instruction. In all three surveys, over 90% of patrons were open to instruction from the librarian.

Survey results also showed that librarians are actively teaching in all three mediums. However, more respondents felt they had received instruction at the physical reference desk than in the online mediums. When asked if the librarian “showed them how to find the information themselves,” 98% at the Information Desk responded positively (combination of “Yes” and “Sort of” responses). Only 96% responded that the librarian provided instruction in the IM survey and 10% fewer (86%) in the corresponding chat survey. The difference in the surveys substantiates transcript analysis which showed that librarians provided more instruction in face-to-face reference than in either chat or IM reference.

Librarians’ efforts to teach are not going unnoticed. An overwhelming majority of patrons indicated that they learned from their reference experience in all three mediums. However, comparison showed that IM patrons responded most positively that they had
learned (92% “yes”). Study 2 dipped to 77%, and Study 3 showed an 88% perception of learning. Those who marked the intermediate “Sort of” response made up 4%, 15%, and 10% respectively. Combining the two responses shows that over 96% perceived they had learned in IM, 92% in chat, and 98% in face-to-face reference. Clearly, patrons perceived that they were learning from the reference transaction. Collectively these responses support the authors’ belief that instruction can and should be practiced from the reference desk, be it physical or virtual, and that reference instruction can be effective in both.

Finally, respondents were asked if they thought IM, chat, or the Information Desk was a good way to learn how to find information. Respondents answering “Yes” accounted for 98%, 92%, and 100% respectively. Respondents were overwhelmingly positive about the service they received in each medium, and more importantly, that service’s ability to provide a learning experience. Here again, face-to-face interaction seems to offer a slight edge over virtual mediums.

Survey 2 included questions about patrons’ experience with co-browsing technology. Over 90% of patrons who reported using co-browsing thought it was a good way to learn. The other 10% thought that co-browsing was “too confusing.” Surprisingly, respondents seemed enthusiastic about co-browsing even though transcript analysis showed a large number of technical difficulties. Perhaps the high rate of satisfaction with co-browsing is attributable to its visual nature. If patrons can see what the librarian is doing and can participate via a shared browser, they may feel they can later repeat the process. Co-browsing allows for textual explanation via the chat window and visual cues in the shared browser window. Certainly, its ability to provide for multiple learning styles is an asset.

The authors were curious how the act of co-browsing might mimic behaviors commonly practiced in face-to-face reference. In addition to questions found in all three surveys, Survey 3 also contained a question asking patrons if the librarian involved them in the search process. Of the 88 responses, only one indicated that the librarian did not involve him or her in the search process. Another two did not answer the question. This left 85 (97%) who marked “yes, the librarian involved me in the search process.” These respondents were asked to indicate how the librarian involved them by selecting from a series of behaviors such as pointing to an area on the computer screen or turning the monitor so that the patron could see. Respondents could choose as many as applied to their reference experience. Fourteen respondents did not select any of the behaviors from the list, despite marking “yes” to the previous question. Therefore, totals are based on the remaining 71 respondents.

All 71 respondents (100%) indicated that the librarian turned the computer monitor towards them so that they could follow the search. Another 57 (80%) noted the librarian pointed to an area on the monitor. The next highest ranked behavior was pointing to an area in the library, with 39 patrons (55%) reporting that the librarian used this technique. Only 23 patrons (32%) reported that the librarian encouraged them to type on the keyboard or use the mouse. Finally, one respondent selected the “Other” category for a write-in comment, stating that the librarian demonstrated how to renew books. Most respondents indicated that the librarian practiced two or more of the above behaviors.
These behaviors at the reference desk are comparable to a co-browse session, in that the patron can be involved on multiple levels. Like co-browsing, involvement at the reference desk begins by viewing the computer screen together. However, transcript analysis does not allow us to see each and every keystroke in the co-browse session, so the level of involvement is not as easily measured. Co-browsing attempts to mimic common behaviors at the reference desk but cannot duplicate simple physical actions such as pointing to an area in the library. Features in co-browse, such as the ability to point to areas of the screen with an arrow, are complicated by technology. Librarians and patrons alike must learn to use the technology while still trying to teach and learn. The simplicity of the physical reference desk makes these actions far easier and thus more likely to occur.

**Conclusion**

Since the advent of complex end-user databases, the once active debate over the instructive role of reference librarians seems passé. These three studies indicate that patrons wanted to be taught regardless of medium, and that librarians responded by providing instruction in all mediums. These patrons’ consistently high desire for instruction reinforces the notion that the ideal teachable moment can be found in reference work. Reference queries are patron initiated and can engage the student in point-of-need active learning.

The question then becomes how should we teach? What techniques are librarians using, what teaching models are they following, and what instructional behaviors are effective in the reference situation? This study attempts to begin this discussion by providing preliminary data on one library’s instructional techniques. One difference between virtual and physical reference does stand out. Instructional techniques measured were used in different proportions in each medium. While professional best practice guidelines such as RUSA’s “Guidelines” dictate consistency of service regardless of medium, librarians need to recognize that instructional techniques may not be a “one size fits all” proposition. Different reference mediums may call for different teaching techniques in order to maximize effective learning.

The findings above draw attention to differences in instructional practices, mediums, and behaviors. Yet the most striking feature of the data is the similarities. In all mediums, librarians provided instruction almost all the time, whether that patron seemed to be asking for it or not. The phrasing of the question and the non-verbal behaviors of the patrons did have some effect on the likelihood of instruction, but according to transcript analysis, that effect was small. Librarians in virtual reference were almost as likely to provide instruction as those at the physical desk, and paraprofessionals almost as often as degree-holding librarians. Patrons for the most part expressed a desire to learn and felt that reference is an effective tool for learning. They were happy with the reference transaction and ready to return. Patrons who visited the library physically were slightly more satisfied than those who visited virtually. While both numbers were quite high, it is interesting to note that the physical reference desk saw slightly higher rates of instruction and user satisfaction.
Further study is needed in the way that instruction is being practiced through reference work. Librarians perform a disservice to patrons if instruction in reference transactions is only a happy accident, practiced without deliberation, research, or care. Library school courses in reference typically focus on sources and reference interview techniques, ignoring the instructive aspect of reference. Greater attention to learning theory in library school is a must, not only in courses on instruction but also in reference classes. With the recent explosion in libraries’ virtual reference presence, further study also is warranted to measure the effectiveness of various teaching techniques and their relationship to differing reference mediums. As reference mediums evolve, librarians will not only have to learn to recognize the “teachable moment” but also to identify strategies to maximize learning potential in each medium.
